**Pulse Oximetry**

The majority of infants attain SaO$_2$ above 95% within 10 minutes of birth. Therefore a failure to do so should prompt a careful assessment for underlying pathology.

Oxygen is a common therapy for very preterm and sick infants. Although it has clearly been associated with significant improvements in neonatal survival and disability, its by-products - free radicals and reactive oxygen species can cause tissue injury and have been associated with ROP and probable oxidative damage in other organs (brain and lung). A number of trials have been undertaken to better define the best oxygen saturations to target in preterm infants, balancing the risk of ROP (with higher saturations) and the risk of pulmonary hypertension and death (with lower saturations). On current evidence our decision is to target preterm infant’s oxygen saturations to be 91-95% until they reach 37 weeks CGA.

**Key Points**

- If oximeter insitu on admission, probe must be released and circulation assessed prior to reapplying probe. Assessment to be documented in comments section of MR489/491.
- Oximeter probe to be placed on right hand on admission – pre-ductal.
- Oximeter probe is to be re-sited at least 2-4 hourly. Document on MR489/491 location of new site (eg. ® LH = re-sited left hand, ® RF = re-sited right foot).
- Do not overtighten strappit – observe hand or foot for swelling, colour change and perfusion.

Different target saturations and alarm limits may be ordered for individual infants with specific problems such as congenital heart disease, congenital diaphragmatic hernia and PPHN and infants with difficult ventilation.

If using a different target range please document in the medical progress notes the target range and reasons.

**Oxygen Saturation Monitor as follows:**

- Infants with respiratory distress or compromise.
- Preterm infants until they reach 34 weeks CGA (unless otherwise documented): this should be then be reviewed daily on ward round until monitor can be ceased.
- Monitoring can be ceased a minimum of 5 days after stopping caffeine and when there are no significant apnoea’s. Mild self-limiting desaturation in well infants is not an indication to continue monitoring.
- The use of histograms to see the average saturations is recommended.
- Monitor for a further five days after supplemental oxygen has been ceased for infants with chronic lung disease.
Monitoring and Observation Frequency

- Respiratory distress for <24 hours (TTN), monitor for a minimum of 4 hours after ceasing respiratory support.
- Stable infants being discharged home on oxygen may have SaO\textsubscript{2} once per shift for two hours.
- Infants receiving a course of caffeine and for a minimum of 5 days following cessation of caffeine.
- NAS infants receiving PO Morphine > 0.9 mg/kg/day.
- Infants nursed prone (i.e. Neural tube defect).

**Cardiac Monitoring**

- All infants with respiratory support (ventilated, CPAP, HHF).
- All infants with apnoea and bradycardia of prematurity - required for 48 hours after last episode of bradycardia.
- Infants receiving a blood transfusion. Remove 2 hours after completion of transfusion.
- Infants having 8 week and 16 week immunisation, monitor for 48 hours.
- Investigation of cardiac arrhythmia.
- All preterm infants until 32 weeks CGA.

**Blood Pressure Monitoring**

There is no consensus on exact definition of hypotension. Normal blood pressure in preterm infants is difficult to define and is based on small numbers. Blood pressure needs to be considered along with history of birth asphyxia, signs of adequate organ perfusion, which includes metabolic acid base balance, urine output and skin perfusion (capillary refill time).

Estimates of systemic blood flow may be obtained from cardiac echocardiogram; this is a better measure of perfusion. An echocardiogram should be part of the investigation of low blood pressure and can be used to re-evaluate any treatment instituted.

Blood pressure increases with gestation, birthweight and postnatal age, particularly over the first 24 hours of life.

See Appendix A – Blood Pressure Normal Limits

**New Admissions**

Monitor on admission and hourly until stable (can omit non-invasive BP if an arterial line is to be promptly inserted).

**Any Unstable Infant - Monitor Hourly**

Other infants requiring hourly monitoring include

- Cardiac disease.
- Renal disease.
- Infants on inotropes.

**Post-Operative**

Refer to Post-Operative Care.
**Non-Invasive BP Monitoring in Stable Infants**

- Infants born < 32 weeks gestation or < 1250 grams and who are < 1 week of age - BD.
- Infants born < 32 weeks or < 1250 grams and who are > 1 week old - daily.
- Infants receiving steroid therapy (including Budesonide) - 8 hourly then daily when dose weaning.
- Infants with O₂ dependency, > 28 days of age, weekly.
- Infants receiving oral morphine > 0.9 mg/kg/day - BD.
- Infants on other vasoactive drugs, Captopril, Sildenafil, Thyroxine, steroids, diuretics, Diazoxide - BD/daily as ordered.

**Factors affecting the reliability of readings include:**

- Size and fit of cuff - Cuff must be attached snugly and cover 2/3 of the limb. Can use either arm or leg.
- State of alertness or agitation of the infant - After cuff application, allow a rest period to ensure the infant is in a restful state when measurement is taken.
- Non-invasive BP may over-estimate BP measurements in VLBW.
- With in-dwelling arterial lines.
  - Small air-bubbles may effect measurement.
  - Peripheral lines tend to read higher than umbilical lines.
  - Occlusion of the tip of the catheter (vessel wall or clot) may dampen the wave and underestimate BP.

**Observation Frequencies - Temperature, Heart Rate, Respiratory Rate**

**Full Observations - Hourly**

- New admissions - first 3 hours - then reassess.
- Infants with unstable vital signs.
- Infants receiving blood transfusion (refer to Blood and Blood Products: Administration for extra observations needed pre and during transfusion).

**Full Observations - 3 or 4 Hourly / Coincide with Cares and Feeds**

- Infants who are tachypnoeic > 60 bpm or tachycardic > 160 bpm.
- Following triple antigen and Hib vaccine - for 48 hours.
- Infants receiving antibiotics.
- Infants with feed intolerance.
- Infants with symptomatic patent ductus arteriosus.
- Infants receiving phototherapy.

**Full Observations - 6 or 8 Hourly / Coincide with Alternate Cares/Feeds**

- Stable infants receiving enteral feeds.
- Stable infants receiving oxygen therapy - and for 5 days after ceasing oxygen.
- Stable infants receiving caffeine therapy - and for 5 days after ceasing caffeine.

**Minimum Observations in the NICU**

Temperature with each feed is performed on infants ready for discharge/level 1 care infants.
